MEXICAN FOSSIL ECHINI

By Robert Tracy Jackson

The collection of fossil Echini reported upon in this paper was submitted to me for study by Dr. T. Wayland Vaughan. All types of new species described herein are in the United States National Museum except that of Lovenia mexicana, which is in the museum of the California Academy of Sciences, San Francisco.

I should express my warm appreciation to my friend Dr. Hubert Lyman Clark for his help in this work. His opinion is of great value, especially in the cidaroids and clypeastroids, for the identifications in these two groups is exceptionally difficult on account of the multiplicity of species, and Dr. Clark is a high authority on both groups. Assistance in stating precisely the localities and the geologic horizons has been kindly rendered by J. M. Muir and Thomas F. Grimsdale.

The regular Echini are represented by only two species of Cidaris and one of Stomopneustes. This last is of exceptional interest, as it is the first recorded occurrence of the genus as found fossil in America. Indeed, its previous occurrence as a fossil anywhere is somewhat doubtful. The clypeastroids, as usual in Tertiary collections, are rather abundant in species and individuals. Of spatangoids there are a number of species, and the specimens are in an exceptionally good state of preservation.
Table 1 shows the localities and the geologic horizons of the species found in the collection.

Dickerson and Kew have published a paper in which Kew, who is the author of the echinoid portion, recognized 12 species of Echini, four of which were described as new. Merle C. Israelsky described six new species of Echini from Mexico and recorded in all 13 species from that region. Errors in localities as cited by Israelsky are corrected in a book by J. M. Muir. Additional fossil Echini from Mexico are included in a paper by the veteran echinologist M. Jules Lambert, who had only a limited amount of material, some 12 specimens, which he referred to eight species, three of which were described as new.

In the material on which the present paper is based 13 species are recorded, six of which are new. In all, 32 species have been recorded from Mexico, 18 of which were described as new.

3 Geology of the Tampico embayment, six +250 pp., illus. American Association of Petroleum Geologists, 1936.
Order CIDAROIDA Duncan

Family CIDARIDAE Gray

Genus CIDARIS Leske

CIDARIS LOVENI Cotteau

A fragment consisting of an interambulacral area and a half-ambulacral area appears referable to this species, although it is considerably larger than the type, which is from the Eocene of St. Bartholomew, West Indies. The Mexican specimen measures 29 mm in height, width of the interambulacrum at the midzone 22 mm, width of the half-ambulacrum at the same zone 3 mm. This, of course, indicates 6 mm as the width of the ambulacral area. This species is recorded qualifiedly as Cidaris cf. loveni by Kew and also by Israelsky as from Tuxpan, based apparently on the same specimen here considered.

Miocene, Tuxpan formation, Tuxpan, Veracruz, Mexico; Dumble and Cummins, collectors, 1908, California Academy of Sciences, locality X 14, one specimen.

CIDARIS THOUARSI Agassiz and Desor

A specimen somewhat crushed but otherwise fairly well preserved is referred to this species. It measures 17 mm in height, width of an ambulacrum at the midzone about 3 mm, width of an interambulacrum at the same zone 14 mm. Cidaris thouarsii occurs in the Recent fauna of the Pacific off the west coast of Mexico. It is of interest that it is found also in the fossil state in Mexico. C. tribuloides, which is abundant in the Recent West Indian fauna, has been found fossil in Cuba.

Miocene, Tuxpan formation, Tuxpan, Veracruz, Mexico; Dumble and Cummins, collectors, 1908, California Academy of Sciences, locality X 14, one specimen.

Order CENTRECHINOIDA Jackson

Suborder STIRODONTA Jackson

Family STOMOPNEUSTIDAE Mortensen

Genus STOMOPNEUSTES Agassiz

STOMOPNEUSTES PRISTINUS, new species

PLATE 12, FIGURE 1

Test low, dome-shaped, ambitus below the midzone, slightly pentagonal in horizontal outline, the ambulacral areas coinciding with
the apices of the pentagon, flattened dorsally, slightly reëntrant about the peristome, otherwise very nearly flat ventrally. Ambulacra wide, measuring about 25 mm in width at the ambitus, ambulacral plates composed of three elements, but this species, like the Recent
*S. variolaris* (Lamarck), has a peculiar arrangement in that every fourth ambulacral plate bears a large primary tubercle that has grown over four plates and hides their sutures. This, with other important details in regard to the Recent species, is considered by Dr. H. L. Clark. Interambulacra with two vertical rows of primary tubercles in each half-area. Diameter of the specimen 81 mm, height 38 mm.

The single known specimen (U.S.N.M. no. 496275) of this new and interesting echinoid is much worn and shows structural detail only in parts of the test. The peristome and periproct are not preserved, or are not visible. The test is thick and solid and gives no evidence of flattening or other distortion.

The genus *Stomopneustes* is known from the Recent species *S. variolaris* (Lamarck) from the southern Pacific Ocean. According to Duncan, a species has been found in the Tertiary of Java, but he queried the statement.

Oligocene, Mesón, Hacienda Tierra Amarilla, about 7 km northwest of the town of Temapache, Canton Túxpan, Veracruz, Mexico; Corona collection, no. 29 (=H176), one specimen.

**Order EXOCYCLOIDA Jackson**

**Suborder CLYPEASTRINA Gregory**

**Family CLYPEASTRIDAE Agassiz**

**Genus CLYPEASTER Lamarck**

**CLYPEASTER MERIDANENSIS Michelin**

Of the species *Clypeaster meridanensis*, described by Michelin from the Tertiary of Merida, Yucatan, there is a fine series of extremely well preserved specimens from Túxpan, Tampico, and Hacienda Santa Fé, Topila, Mexico. The largest specimen, from a small quarry in the town of Túxpan, collected by D. R. Semmes, no. 82, measures 160 mm in length, 142 mm in width at the widest part through ambulacra II and IV, and 27 mm in height.

There are 12 specimens of this species from the Miocene of Túxpan, Veracruz, Mexico, and two from the Oligocene Mesón formation of Hacienda Santa Fé, Topila, Veracruz. Also there is a 4-rayed specimen and a fragment from 1 mile north of Tampico and on the opposite

---

side of Laguna del Carpintero from it; California Academy of Sciences, locality X 34. A specimen with petals broader and poriferous areas wider than is usual in the species as a variant is from Túxpan, Veracruz, California Academy of Sciences, locality X 14.

Lambert also records this species from Túxpan.

**CLYPEASTER MARINANUS, new species**

**Plate 12, Figure 2; Plate 13, Figure 1**

Test elongate, low, subpentagonal in outline, very thin on the borders, center only slightly elevated, ventrally nearly flat, slightly reëntrant around the mouth. Ambulacral petals relatively short, slightly curved, open at the tips, nearly flush with the surface of the test, poriferous areas not sunken. Apical disk slightly anterior to the center. Periproct near the posterior end; in a specimen 72 mm long the periproct is 6 mm from the border. Tubercles are small dorsally and closely associated; ventrally they are larger and more deeply sunken.

There is a rather large series of specimens of this species from several localities. The specimen selected as the type, H 120 (U.S.N.M. no. 496276), from Chamal on the north side of Soto la Marina River, measures 102 mm in length, 94 mm in width, and about 20 mm in height. Another specimen, from Hacienda Santa Fé, Topila, measures 116 mm in length, 98 mm in width, and about 17 mm in height.

*Clupeaster marinanus* approaches in character nearest to *C. rogersi* Morton but differs from that in having the test flatter and being much thinner at the margin and less deeply reëntrant around the mouth. Also the ambulacral petals are shorter, narrower, and less curved, and the poriferous areas are narrower in *rogersi*. *C. marinanus* differs from *C. staubi* Lambert, which also occurs east of Soto la Marina, in that the test of *marinanus* is much less conically elevated and much less pentagonal in outline than *staubi*.

Oligocene, Mesón formation, at the following localities: Chamal, Soto la Marina River, Tamaulipas, Mexico, Corona collection, six specimens including the holotype; Mesón, Hacienda Santa Fé, Topila, Veracruz, six specimens; Lot 214 Hacienda Chinampa, 10 km east of town of Chinampa, Canton Túxpan, Veracruz, just above the main *Lepidocyclina gigas* beds, top of Mesón formation, three small immature specimens; east of Ozuluama, one specimen; Mesón formation, Aguilá Colony, about 4 km northwest of the cathedral, Tampico, Mexico, one specimen; north of Arbol Grande, between 3,700 and 4,300 feet north of Arbol Grande station, near Tampico, Mexico, several fragments; cut on street railway between Dona Cecilia and Tampico, Mexico, one fragment, California Academy of Sciences, locality X 118.

Clypeaster sp. a Kew, Proc. California Acad. Sci., ser. 4, vol. 7, no. 5, table facing p. 128 (for localities listed), pp. 130, 131, pl. 23, fig. 2; pl. 24, fig. 2, 1917.

Test moderately high, pentagonal, elongate anteriorly, truncate posteriorly, with thick rounded margin, dorsally elevated into a low dome, ventrally reentrant to the moderately sunken peristome. Apical disk small, a little anterior to the center of the test. Periproct near the posterior border of the test, 5 mm from it in the type, which measures 96 mm in length. Ambulacral petals open at the tips, poriferous areas narrow, moderately depressed, nonporiferous areas only moderately elevated.

There is a rather large number of specimens of this species. The one selected as the type (U.S.N.M. no. 496278) measures 96 mm in length, 80 mm in width, and 25 mm in height. With all the species assigned to the genus Clypeaster, it is annoying to make still another, but these specimens cannot be made to fit into any species known. C. topilanus is nearest to C. planipetalus Cotteau, but it differs from that in having shorter petals and being less open at the tips; also the petals are straighter and the poriferous areas are narrower than they are in planipetalus. C. topilanus is more massive and more strongly pentagonal in outline than C. sanrafaelensis Israelsky, which is from the Tampico region.

The species that Kew figured as Clypeaster species a is evidently the same as that described here as new. Kew did not give any description of his species a, but it is listed in his table of species from the "San Fernando formation and associated beds." As noted on page 125 (footnote) of Dickerson and Kew's paper, the name "San Fernando" being preoccupied, the name "San Rafael" was proposed as a substitute by Prof. E. T. Dumble. That name has now been dropped, as it was a synonym of the Mesón formation. Kew gave as localities for his species a: Salitre Ranch, Tamaulipas; and hill at extreme north of La Puerta Range, Hacienda Santa Fé, Topila, Veracruz.

In the material at hand there is a fine series from the Mesón formation at abandoned Corona camp, Hacienda Santa Fé, Topila, Veracruz, Mexico, 16 specimens. One specimen without locality is marked locality X 83a, California Academy of Sciences.
1, Clypeaster marinanus, new species, Mesón formation, Hacienda Santa Fé, Topila, Mexico, locality M19V, paratype, ventral view, U.S.N.M. no. 46277; 2, C. topilanus, new species, same formation and locality, holotype, dorsal view, U.S.N.M. no. 496278; 3, C. topilanus, same formation and locality, Corona collection no. 14, paratype, ventral view, U.S.N.M. no. 496279; 4, Laganum leptum, new species, Mesón formation, on line of Transcontinental Railroad, lot 145, Hacienda Chinampa, 8 km east of town of Chinampa, Canton Túxpan, Veracruz, at the first cut examined November 28, 1920, holotype, dorsal view, U.S.N.M. no. 496280. (Five-sixths natural size.)
Eupatagus mexicanus, new species, Mesón formation, Hacienda Santa Fé, Topilla, Mexico, Corona collection no. 1, holotype, dorsal view. U.S.N.M. no. 496281. The figure is slightly foreshortened. (Five-sixths natural size.)
1, _Eupalagrus mexicanus_, new species, Mesón formation, Hacienda Santa Fé, Topila, Mexico, Corona collection no. 1, holotype, ventral view of same specimen as pl. 11; 2, _Loricina mexicana_, new species, Rancho Nuevo, 2.5 km WSW of Mesón, Canton Túxpan, Veracruz, W. F. Cummins collector, Calif. Acad. Sci., locality X62, holotype, dorsal view. 3, _L. mexicana_, same locality and collector, paratype, ventral view of a larger specimen than fig. 2. (Five-sixths natural size.)
Test very nearly circular, very flat and thin. Apical disk central, peristome probably the same, but invisible. Ambulacral petals short, wide, obovate. Poriferous areas wide. Periproct very near to, being only 2 mm from, the posterior border of the test.

The single known specimen (U.S.N.M. no. 496280) measures 38 mm in length, 35 mm in width, and about 5 mm in height. This species approaches perhaps nearest to Laganum johnsoni Twitchell, from the Eocene of Alabama. It differs from johnsoni in the extreme thinness of the test and in the shortness and obovate form of the petals in leptum.

L. leptum was collected by Dr. T. W. Vaughan in the Oligocene Mesón formation on the line of the Transcontinental Railroad, lot 145, Hacienda Chinampa, 8 km east of the town of Chinampa, Canton Túxpan, Veracruz, Mexico, at the first cut examined, November 28, 1920.

Family SCUTELLIDAE Agassiz

Genus SCUTELLA Lamarck

SCUTELLA CAZONESENSIS Kew

This species is represented by a fragmentary but very well preserved specimen of an individual almost exactly the same size as the one figured by Kew.

The specimen here considered is from La Cuesta, Soto la Marina River, Corona collection, no. 28. The geologic horizon is not definitely known, but is either upper Mesón or Túxpan.

Suborder SPATANGINA Jackson

Family HEMIASTERIDAE H. L. Clark

Genus AGASSIZIA Valenciennes

AGASSIZIA CLEVEI Cotteau

Two specimens are referred to this species. The larger of the two as a variant shows considerable resemblance to A. inflata Jackson.
